THE DECAY RESISTANCE OF DOUGLAS FIR, MACROCARPA, LAWSON CYPRESS AND EUROPEAN LARCH FRAMING SUMMARY OF RESULTS AFTER 52 WEEKS EXPOSURE

Summary

Short pieces of 90 x 45mm framing timber of Douglas fir (*Pseudotsuga menziesii*), European larch (*Larix decidua*), Lawson cypress (*Chamaecyparis lawsoniana*), macrocarpa (*Cupressus macrocarpa*) and radiata pine (*Pinus radiata*) were inoculated with brown rot decay fungi and installed in filleted stacks in sealed tanks. The groups included heartwood, sapwood, LOSP treated and boron treated samples.

After 12 months there was severe decay in the untreated radiata pine and in the untreated sapwood of the other species. Decay was becoming established in the untreated heartwood of Douglas fir and larch but only isolated minor spots on the macrocarpa and Lawson cypress. There was isolated light decay in LOSP treated Lawson cypress and macrocarpa, mainly at the joints.

Introduction

New building regulations relating to the durability of timber framing have impacted on the use of species that previously had been used without preservative treatment. These include Douglas fir (*Pseudotsuga menziesii*), European larch (*Larix decidua*), Lawson cypress (*Chamaecyparis lawsoniana*), macrocarpa (*Cupressus macrocarpa*) and Mexican cypress (*C. lusitanica*). These species can not now be used in many situations, or require preservative treatment of the sapwood to the H1.2 specification. This test was established to determine the relative durability of framing from these species, including sapwood that had been preservative treated with boron or light organic solvent preservatives (LOSP).

TEST GROUPS AND INSTALLATION

Fourteen species/treatment combinations were included as follows:

- 1. Radiata pine, untreated, kiln-dried controls.
- 2. Douglas fir, untreated air-dried sapwood.
- 3. Douglas fir, untreated air-dried heartwood.
- 4. Douglas fir, boron treated (pressure diffusion), air-dried sapwood.
- 5. European larch, untreated air-dried sapwood.
- 6. European larch, untreated air-dried heartwood.
- 7. Lawson cypress, untreated air-dried sapwood.
- 8. Lawson cypress, untreated air-dried heartwood.
- 9. Lawson cypress, boron treated (pressure diffusion), air-dried sapwood.
- 10. Lawson cypress, air-dried LOSP treated (tributyltin naphthenate), sapwood.
- 11. Macrocarpa, untreated air-dried sapwood.
- 12. Macrocarpa, untreated air-dried heartwood.
- 13. Macrocarpa, boron treated (pressure diffusion), air-dried sapwood.
- 14. Macrocarpa, air-dried LOSP treated (tributyltin naphthenate), sapwood.

There were ten samples of dry planer gauged 90 x 45mm framing, 750mm long, in each group. The radiata pine samples were predominantly sapwood but the sapwood samples of the other species all contained a high percentage of heartwood. A joint was created at one end of each sample by cutting a 90mm long section off and then fixing it back onto the sample with stainless steel staples. Each set of samples was soaked in water for two hours before feeder blocks were attached.

An *Antrodia xantha* feeder block was placed at one end of each sample and an Auckland brown rot (this fungus has been provisionally identified as *Antrodia vallantii*) feeder block at the other. The end with the *A. xantha* feeder block on it was marked with an "X". At the jointed end the feeder block was placed so that it was across the stapled joint. Five samples from each group had *A. xantha* feeder blocks at the jointed end and the other five had Auckland brown rot.

The samples were arranged randomly in filleted stacks, in sealed tanks, in an area where the relative humidity is greater than 95% and the temperature is 25°C. The progress of decay on the samples was assessed after four, 12, 26, 38 and 52 weeks.

ASSESSMENT METHODS

Samples were weighed and this data was compared with estimated oven dry weights to give the approximate moisture content for each sample. Decay mycelium on the framing, the soundness of the wood and the amounts of moulds present were recorded. At the 26, 38 and 52-week assessment the staples were removed from the joint and the internal surfaces were assessed for decay. The decay and mould rating systems were as follows:

Mycelium Spread Rating System

- 1 = No mycelium development onto the framing surface.
- 2 = Mycelium from the feeder block on the framing surface, spread less than 5mm.
- 3 = Active mycelium over <50% of the plate/dwang surface.
- 4 = Mycelium over >50% the plate/dwang surface.
- 5 = Extensive mycelium development over all framing components.

Decay Rating System

- 10 = No decay or insect damage.
- T = Serious discolouration not positively identified as decay.
- 9 = First stages of decay or damage up to 3% of cross-section.
- 8 = Lightly established decay, 3-10% of cross-section.
- 7 = Well established decay, 10-30% of cross section.
- 6 = Deep established decay, 30-50% of cross section.
- 4 = Severe decay, nearing failure, more than 50% of the cross section.
- 0 =Failed, disintegrating.

Mould Rating System

- 1 = No mould.
- 2 = Light mould or a few scattered spots.
- 3 = Widespread scattered mould spots.
- 4 = Patches of mould, <50% of the surfaces covered.
- 5 = Extensive or widespread mould, >50% of the surfaces covered.

RESULTS

The estimated moisture content and mould ratings for each assessment period are summarised in Table 1. Individual sample assessment results are in Appendix I.

TABLE 1
Average Moisture Content and Mould Ratings

| Lawson Cypress heartwood | 30.8 | 35.0 | 40.3 | 38.6 | 3.1 | 4.0 | 4.2 | 4.8 | |
| Lawson Cypress Boron | 36.9 | 48.0 | 59.3 | 58.3 | 2.8 | 3.7 | 3.7 | 4.1 | |
| Lawson Cypress LOSP | 33.4 | 36.7 | 41.5 | 38.9 | 3.7 | 4.6 | 4.6 | 4.8 | |

The average moisture content of samples increased gradually over the first 38 weeks of the trial but decreased slightly over the last 14 weeks of the trial after weekly spraying of the samples was stopped. The moisture content of most sound samples remained in the 30-45% range. The exceptions were boron treated samples, where there were a few samples above 60% moisture content in all species groups. The weights of the untreated radiata pine and some of the untreated sapwood samples have fallen noticeably since the 38-week assessment, due to decay, and this has given falsely low estimates of moisture content in these groups.

Moulds on samples had developed to the point where most samples had moderate-severe discolouration. On some of the more decayed samples it was difficult to determine whether surface discolouration was mould or staining from degenerated decay mycelium. The most severely infected samples were the Lawson cypress, which contained some mould and sapstain at the beginning of the trial, and LOSP treated samples. The least affected were the untreated larch, Douglas fir and macrocarpa heartwood samples. A substantial amount of pale pink, velvety mould developed on boron treated samples in the 38-52 week period.

After only one week's exposure decay mycelium had begun to spread from the feeder blocks onto the surface of the control samples. However, as the trial progressed, many of the feeder blocks became covered with moulds and there was little mycelium development from them, particularly on the preservative treated samples and the untreated heartwood samples. Mycelium spread ratings are summarised in Table 2. Where there was significant mycelium development, this tended to spread to adjacent samples and along fillets to samples in other layers. This resulted in large patches of mycelium, mainly Auckland brown rot, covering parts of several samples, including heartwood, and extending over more than one layer (Figures 3, 7, 8 and 12). There were samples where Auckland brown rot mycelium did not appear to have spread from the original feeder block but had developed away from the feeder block from an outside infection

point (Figure 3). The *Antrodia xantha* mycelium was much less visible and usually restricted to the sample that it had originally developed on (Figure 6).

¹ Index of condition is the average decay rating for all of the items in a group.

The sapwood on the untreated larch samples and seven of the untreated Douglas fir samples contained severe decay and this was spreading into the heartwood of the same samples (Figure 6). The untreated Larch and Douglas fir heartwood samples also contained occasional patches of decay (Figure 10).

In the macrocarpa and Lawson cypress sapwood samples the sapwood section of the samples generally contained severe decay. However, the decay stopped abruptly at the heartwood, even where there was extensive mycelium cover over the surface of the heartwood (Figure 4). There were minor or lightly established patches of surface decay on one sample each of macrocarpa and Lawson cypress heartwood (Figures 5 and 9).

Two LOSP treated macrocarpa samples contained minor decay, one on the surface and one at a joint, and one Lawson cypress sample contained moderate decay both on the surface and in the joint. Otherwise there was no mycelium spread on the LOSP treated samples and no decay.

None of the boron treated Douglas fir, Lawson cypress or macrocarpa samples had any surface decay. There was minor internal decay in the heartwood section at the joint in one Douglas fir sample (Figure 11).

Decay ratings in the joints are summarised in Table 4. Overall the ratings were similar for surface and joint decay but in the Larch heartwood decay was greater in the joint than on the surface at the Auckland brown rot end. In the Douglas fir sapwood Auckland brown rot was more severe on the surface than in the joint.

Discussion

The untreated sapwood of all species contains a significant amount of decay (Figure 1). While untreated radiata pine has decayed more rapidly than the other species the extent of the decay in the sapwood of the other species confirms that significant amounts of sapwood should be avoided where there is a risk that the framing could become wet.

The heartwood of Douglas fir and larch has shown some resistance to decay but this is slowly being overcome where decay fungi are vigorously active. The macrocarpa and Lawson cypress heartwood have shown much greater resistance to decay as only minor decay was present after the first 12 months (Figure 2). The major difference between the untreated heartwood and the LOSP treated framing groups after 12 months is that the decay mycelium has spread much more readily on the surface of the heartwood samples.

Boron diffusion treatment has been almost totally successful in preventing decay over a twelvemonth exposure period. Minor decay in the heartwood of one sample is probably the result of poor preservative treatment into the heartwood, something that is to be expected with this type of treatment. Heartwood penetration is not a requirement of the H1.2 treatment specification.

Apart from one Lawson cypress sample, the LOSP treated macrocarpa and Lawson cypress were largely free of decay on the surface. There were minor decay patches on the surface of one macrocarpa sample and internally in the sapwood of another but overall LOSP treatment has largely prevented decay in the first 12 months. The decay that is present in three samples suggests that occasional pieces of LOSP treated sapwood will be susceptible to decay if exposed to wetting for prolonged periods.

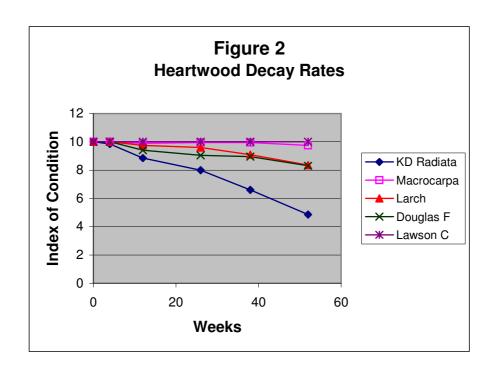

Figure 3 – Layer 6 (2nd from top) Tank 2, after 52 weeks exposure. Extensive Auckland brown rot mycelium at both ends of mainly untreated sapwood samples, some spreading from infected samples in layers above and below. Although sample LS5A had severe mould infection and was surrounded by decaying samples, there was no decay on it.

Figure 4 – Sample MS12A, Layer 6, Tank 2 after 52 weeks exposure. Macrocarpa sapwood sample showing severe Auckland brown rot decay in the sapwood stopping abruptly at the heartwood boundary.

Figure 5 – Sample LH6A, Layer 5, Tank 2 after 52 weeks exposure. This Lawson cypress heartwood sample was severely stained and largely covered by Auckland brown rot mycelium. Although there was minor patch of decay in the joint the sample was otherwise sound.

Figure 6 – Sample LAS3, Layer 4, Tank 2 after 52 weeks exposure. Larch sapwood sample with severe decay extending through the sapwood and into the heartwood. This decay is typical of *Antrodia xantha*, with very little visible mycelium on the surface even when the wood is severely decayed.

Figure 7 – Layer 2 (2nd from bottom) Tank 2, after 52 weeks exposure. Five samples, Larch sapwood, Larch heartwood, Lawson cypress sapwood and radiata pine have extensive Auckland brown rot mycelium on them and this has spread between samples. All contained moderate-severe decay. Sample LS10C is a boron treated Lawson cypress sample with extensive pale coloured mould on the surface but no decay.

Figure 8 – Layer 7 (Top layer) in Tank 1 after 52 weeks exposure. The sample at the right hand end is M15AH, macrocarpa heartwood. Although there was extensive Auckland brown rot mycelium on the surface, spreading from the sample underneath, there was only minor decay associated with it. The other sample with extensive mycelium on it, LS1B (Lawson cypress sapwood) was badly stained but contained very little decay.

Figure 9 – Sample M15AH, Layer 7, Tank 1 after 52 weeks exposure. Extensive Auckland brown rot mycelium on the surface and through the joint of a macrocarpa heartwood sample but only small patches of lightly established decay.

Figure 10 – Sample LAH7 (Larch heartwood), Layer 7, Tank 1 after 52 weeks exposure. There was a small amount of Auckland brown rot mycelium and minor decay on one edge but moderate-severe decay in the joint. Extensive mycelium on the adjacent Lawson cypress sapwood sample, LS1B, appeared to have spread from sample LAH7 but had not caused any significant decay in the Lawson cypress.

Figure 11 – Sample LS6C (boron treated Lawson cypress sapwood), Layer 6, Tank 1 after 52 weeks exposure. There was extensive mould and sapstain on this sample including the joint surfaces but no decay.

Figure 12 – Layer 2 (2nd from bottom) in Tank 1 after 52 weeks exposure. The four samples from the right hand side are untreated sapwood, Douglas fir, larch, Lawson cypress and macrocarpa, all with moderate –severe decay in the sapwood. The fifth sample is boron treated Lawson cypress with extensive mould and no decay. Sample LAS7 is untreated larch sapwood also decaying. The third sample from the left is an LOSP treated Lawson cypress sapwood sample containing moderate decay under extensive Auckland brown rot mycelium, which appeared to have spread from the layer underneath.
